# CSCI 210: Computer Architecture Lecture 5: MIPS, Number Systems

Stephen Checkoway

Oberlin College
Feb. 28, 2022

Slides from Cynthia Taylor

#### Announcements

Problem Set 1 due Friday 23:59

Office hours Tuesday 13:30–14:30

#### Memory Instructions

```
lw $t0, 0($t1)
-$t0 = Mem[$t1+0]
- Loads 4 bytes from $t1, $t1+1, $t1+2, and $t1+3

sw $t0, 4($t1)
- Mem[$t1+4] = $t0
- Stores 4 bytes at $t1+4, $t1+5, $t1+6, and $t1+7
```

 These instructions are the cornerstones of our being able to go to and from memory

## Memory Operand Example 1

• C code:

```
g = h + A[8];
```

- g in \$s1, h in \$s2, base address of A in \$s3, A is an array of 4 byte ints
- Compiled MIPS code:
  - Index 8 requires offset of 32

```
lw $t0, 32($s3)
add $s1, $s2, $t0
```

#### Translate to MIPS

- C code: g = h + A[5];
  - g in \$s1, h in \$s2, base address of A in \$s3.
  - A is an array of 4-byte ints
- A. lw \$t0, 5(\$s3) add \$s1, \$s2, \$t0
- B. lw \$t0, 20(\$s3) add \$s1, \$s2, \$t0
- C. | lw \$t0, \$s5 add \$s1, \$s2, \$t0
- D. | lw \$t0, \$s3 add \$s1, \$s2, \$t0

## Memory Operand Example 2

• C code:

```
A[12] = h + A[8];
- h in $s2, base address of A in $s3
```

- Compiled MIPS code:
  - Index 8 requires offset of 32

```
lw $t0, 32($s3)  # load word
add $t0, $s2, $t0
sw $t0, 48($s3)  # store word
```

When a 2-byte word is stored in byte-addressed memory (occupying two consecutive bytes), is the most significant byte (MSB) stored in the lower address or the higher address?

```
A. Low \begin{bmatrix} 0 & 0000 & 1111 \\ 1 & 0000 & 0000 \end{bmatrix} = 15
B. High \begin{bmatrix} 0 & 0000 & 0000 \\ 1 & 0000 & 1111 \end{bmatrix} = 15
```

C. It Depends

## Byte ordering

- Big-endian: Most significant byte in lowest address
  - MIPS, Motorola 68000, PowerPC (usually), SPARC (usually), ...
- Little-endian: Most significant byte in highest address
  - Intel x86, x86-64, ARM (usually), ...
- Bi-endian: Switchable between big and little endian
  - ARM, PowerPC, Alpha, SPARC, ...
- Middle-endian/mixed-endian
  - Bytes not stored in either order, at least in some cases

Big-endian means most significant byte/digit/piece comes first, little-endian means least significant byte/digit/piece comes first. Mixed-endian means not in order.

Which row of the table correctly identifies the endianness of date formats?

|   | US (MM-DD-YYYY) | Most of the world (DD-MM-YYYY) | ISO 8601 (YYYY-MM-DD) |
|---|-----------------|--------------------------------|-----------------------|
| Α | Little          | Mixed                          | Big                   |
| В | Big             | Little                         | Mixed                 |
| С | Mixed           | Little                         | Big                   |
| D | Mixed           | Big                            | Little                |
| Е | Little          | Big                            | Mixed                 |

### Immediate Operands

Constant data specified in an instruction

```
- addi $s3, $s3, 4
- li $t0, -25  # Pseudoinstruction: addi $t0, $zero, -25
- ori $v0, $t8, 1
```

#### **Pseudoinstructions**

```
    move dest, src => add dest, $zero, src
    subi dest, src, imm => addi dest, src, -imm
    li dest, imm => addi dest, $zero, imm
```

 More complicated expansions are possible, MARS simulator will show you how it expands pseudoinstructions

## Subtract 2 from \$s0 and store in register \$s1

```
A. addi $s0, $s1, -2
```

E. More than one of the above

## MIPS Design Principles

- Simplicity favors regularity
  - fixed size instructions
  - small number of instruction formats
- Smaller is faster
  - limited instruction set
  - limited number of registers in register file
- Make the common case fast
  - arithmetic operands from the register file (load-store machine)
  - allow instructions to contain immediate operands

## Loading a large number into a register

- Immediates are limited to 16 bits
  - -32768 to 32767 or 0 to 65535
- Numbers outside this range need to be loaded into registers before being used
- load upper immediate instruction sets the most-significant 16 bits of a register
  - -lui \$t0, 0x1234
     ori \$t0, \$t0, 0x5678
- When li is given a value that's too large, the assembler expands it to lui/ori

## MIPS Questions?

## Why we need to learn binary (and other number systems)

- Fundamental to how your computer works
  - Will need a good grasp of binary to understand things like logical operations
  - Will need to translate to binary to work out examples

 Need to understand it to understand many things like network protocols (IP addresses), bit masking, etc.

#### **Positional Notation**

- The meaning of a digit depends on its position in a number.
- A number, written as the sequence of digits  $d_n d_{n-1} ... d_2 d_1 d_0$  in base b represents the value

$$d_n * b^n + d_{n-1} * b^{n-1} + ... + d_2 * b^2 + d_1 * b^1 + d_0 * b^0$$

#### Consider 101

• In base 10, it represents the number 101 (one hundred one) =

• In base 2,  $101_2 =$ 

• In base 8,  $101_8 =$ 

$$101_5 = ?$$

A. 26

B. 51

C. 126

D. 130

A. -10

B. 8

C. 10

D. -30

### Binary: Base 2

Used by computers

• A number, written as the sequence of digits  $d_n d_{n-1} ... d_2 d_1 d_0$  where d is in {0, 1}, represents the value

$$d_n * 2^n + d_{n-1} * 2^{n-1} + ... + d_2 * 2^2 + d_1 * 2^1 + d_0 * 2^0$$

### Computers Use Binary Because

A. Decimal takes too much space

B. It's easier to do math with binary

C. It is easy to represent two states (on/off) with electricity

D. None of the above

#### Decimal: Base 10

Used by humans

• A number, written as the sequence of digits  $d_n d_{n-1} ... d_2 d_1 d_0$  where d is in  $\{0,1,2,3,4,5,6,7,8,9\}$ , represents the value  $d_n * 10^n + d_{n-1} * 10^{n-1} + ... + d_2 * 10^2 + d_1 * 10^1 + d_0 * 10^0$ 

#### Hexadecimal: Base 16

- Like binary, but shorter!
- Each digit is a "nibble", or half a byte (4 bits)
- Indicated by prefacing number with 0x (usually)

• A number, written as the sequence of digits  $d_n d_{n-1} ... d_2 d_1 d_0$  where d is in {0,1,2,3,4,5,6,7,8,9,A,B,C,D,E,F}, represents the value

$$d_n * 16^n + d_{n-1} * 16^{n-1} + ... + d_2 * 16^2 + d_1 * 16^1 + d_0 * 16^0$$

#### Octal: Base 8

- Sometimes used to shorten binary
  - Used to specify UNIX permissions (remember 241?)

• A number, written as the sequence of digits  $d_n d_{n-1} ... d_2 d_1 d_0$  where d is in  $\{0,1,2,3,4,5,6,7\}$ , represents the value

$$d_n * 8^n + d_{n-1} * 8^{n-1} + ... + d_2 * 8^2 + d_1 * 8^1 + d_0 * 8^0$$

$$31_8 = ?_{10}$$

- A. 24
- B. 25
- C. 200
- D. 208
- E. None of the above

## Reading

- Next lecture: Negatives in binary
  - Section 2.4

Problem Set 1 – due Friday
