# Announcements

Homework 0 is up on the website

# Goals for Today

- Basics of Racket
- How do we make choice (i.e., conditionals, etc.)?
- How do we construct and use procedures?

# Introducing Racket

When we talk about code/Racket in this class, I will do my best to use `Font in This Text` to differentiate what is description and what is code  
PowerPoint *will* mess up my “quotation marks”

# Why Racket for CS 275?

All LISP-type languages have lists as the main data structure

- Programs are lists
- Data are lists
- Racket programs can reason about other programs. This makes Racket useful for thinking about programming languages in general.

Racket is a different programming paradigm

- Python, Java, C and other languages are imperative languages. Programs in these languages do their work by changing data stored in variables
- Racket programs can be written as functional programs—they compute by evaluating functions and avoid variable assignments.

# Why Racket for CS 275?

Racket is very elegant. It is much less verbose than Java, for instance, which means it is easier to see what is happening in a Racket program.

I think its fun.

It lets you learn functional programming without a lot of extra features.

# Racket Basics

We are used to **basic values** in most languages

- Numbers (Integers & Floats)
- Strings
- Booleans

We are also accustomed to **procedures/functions**  
which act on elements of these types

These also can look different depending on the language!  
'banana' is invalid Java, but valid Python

# Arithmetic/logical/string operations

$3 + 5$

$x \cdot (4 + y + z)$

$x \text{ AND } y$

$x \text{ OR } y \text{ OR } z$

"hello" + " " + "world" (

**Language Design Statement:** you know the *semantics* of these terms, even if this *syntax* is not that of a language you've learned before

# Everything is prefix in Racket

## Language Design Statement:

The order that a language has the operators and operands is *arbitrary*.

In Racket, you put the operator or function call *\*first\** (prefix form)

`(< x 2)` instead of `x < 2`

# Equivalent operations in Racket

$3 + 5$       `(+ 3 5)`

$x \cdot (4 + y + z)$       `(* x (+ 4 y z))`

$x \text{ AND } y$       `(and x y)`

$x \text{ OR } y \text{ OR } z$       `(or x y z)`

`"hello" + " " + "world"`      `(string-append "hello" " " "world")`

# Some basic data types and variables in Racket

Numbers: `83`, `-6`, `25.23`

Strings: `"this is a string"`

Booleans: `#t`, `#f`

We can define variables\* using `define`:

```
(define department "CSCI")
```

```
(define course-number 275)
```

```
(define instructor "Stephen Checkoway")
```

\* These are not really variables; they're just names we give to some values

**In most languages, we would compute the arithmetic mean (average) of two numbers (or variables holding numbers) as  $(x + y) / 2$ . How do we do this in Racket?**

A.  $(x + y) / 2$

B.  $((x + y) / 2)$

C.  $(+ x y / 2)$

D.  $(+ (/ x y) 2)$

E.  $(/ (+ x y) 2)$

# What do you think these examples will evaluate to?

`(+ 5 2)`

`(zero? x)`

`(or (and #t #f) (and #t #t))`

`(+ (- 1 0) (- 2 3))`

# What do you think these examples will evaluate to?

`(+ 5 2)`

7

`(zero? x)`

Depends on `x`

`(or (and #t #f) (and #t #t))`

`#t`

`(+ (- 1 0) (- 2 3))`

0

# Procedures in Racket

All the examples we saw on the previous example - e.g. `(zero? X)` and `(+ (- 1 0) (- 2 3))` – are calls to **procedures**

In general, the structure of a procedure call in Racket is:

`(name-of-procedure arg1 arg2 ... argn)`

The **parentheses** here are the *call* to `name-of-procedure`

The arguments are given after the procedure's name, separated by spaces

# Procedure calls and special forms

When presented with a sequence `(foo arg1 arg2 ...)` Racket looks at the first element of the sequence (here, `foo`)

**If `foo` is a special form**, Racket follows special instructions (`define`, `and`, etc.)

**If `foo` is a procedure** (built-in or made by you), it applies that procedure to the arguments and returns the result

**Otherwise, error!**

This is the most common error in the first couple weeks of class!

`(1 2 3)` is an error because `1` is not special form or procedure

# Special Form: `define`

Giving names to values – useful!  
However, these are not variables.

```
(define id s-exp)
```

The `define` special form binds an identifier to a value

This modifies the *environment*, the mapping of identifiers to values

```
(define hi "Hello")
```

```
(define professors `("Molly" "Steve" "Cynthia"))
```

```
(third professors) => "Cynthia"
```

```
(define x (+ 20 100))
```

**Whatever is in `s-exp` is evaluated**, so `x` is bound to 120

# Predicates

Style: predicates in Racket will always have ? as the last character (they are asking a question!)

Racket has a bunch of procedures that return `#t` if its argument satisfies some property

<code>(zero? x)</code>	returns <code>#t</code> if <code>x</code> is equal to 0
<code>(empty? x)</code>	returns <code>#t</code> if <code>x</code> is the empty list
<code>(positive? X)</code>	returns <code>#t</code> if <code>x</code> is a positive number
<code>(number? x)</code>	returns <code>#t</code> if <code>x</code> is a number

# Tests for equality

**Most of the time: Use `equal?`?**

`(equal? a b)` compares structures recursively

Are you dealing with numbers? **Use `=`**

`(= a b)` compares only numbers, cannot be used for anything else

`eq?` / `eqv?` are about referring to the same object in memory;  
sometimes useful when you care about literal equality

# If expression

```
(if test-exp then-exp else-exp)
```

If `test-exp` evaluates to *anything other than* `#f`, then the whole expression evaluates to the evaluation of `then-exp`

If `test-exp` evaluates to `#f`, then the whole if expression evaluates to the evaluation of `else-exp`

```
(if (= x y)
     (+ x 2)
     y)
```

```
(if (empty? lst)
    "The list is empty"
    "The list is not empty")
```

# Conditional expressions

```
(cond [test-exp1 exp1] ... [test-expn expn])
```

Evaluates the `test-exp` expressions in turn

The first one that evaluates to something other than `#f` has its corresponding `exp` evaluated - this becomes the value of the whole expression

We can (and should!) use `else` as the last test expression

```
(cond [(zero? x) 0]
      [(> x 0) 1]
      [else -1])
```

If your program is more than just a *\*very simple\** if statement, use `cond`. It's good style.

```
(define foo 12)
(cond [(< foo 2) #t]
      [(>= foo 10) #f]
      [(not (zero? foo)) #t]
      [else (error "there is a problem!")])
```

What does this code evaluate to?

- A. #t
- B. #f
- C. #t or #f, depends on the run
- D. Error
- E. Something else

# Some questions

```
(define foo 12)
(cond [(< foo 2) #t]
      [(>= foo 10) #f]
      [(not (zero? foo)) #t]
      [else (error "there is a problem!")])
```

1. How can I get the `cond` to take an argument, rather than just reference a “global” `foo`?
2. How do I “save” code like that above to be able to reuse it? (i.e. a function!)
  - How is/isn’t this related to using `define` to bind identifiers?

# Creating procedures: `lambda`

Procedures are created using the `lambda` special form

```
(lambda parameters body ...)
```

`parameters` is an unevaluated list of identifiers which will be bound to the values of the procedure's arguments when the procedure is called

`body` is a sequence of s-expressions that form the body of the procedure, they're evaluated in turn

```
(lambda (x y)
  (/ (+ x y) 2))
(lambda (name)
  (displayln "Hello ")
  (displayln name))
```

# Naming Lambdas

Given we have a lambda, we can use it and call it

```
( (lambda (x) (+ x 2)) 4 )
```

This will evaluate to 6. However, this current structure doesn't allow us to *reuse* the lambda with a different input.

We already have a way to bind a value to an identifier ("name"): that's `define`.

We know `define` attaches a name to an evaluated value

```
(define x (+ 20 100))
```

 means `x` is bound to 120

So what does a lambda evaluate to? Anything?

# BIG IMPORTANT SLIDE

Unlike procedures in most languages, in Racket there is a notion that `lambdas are values & so can be evaluated`

- `lambdas` are like numbers, strings, lists, etc.
- We can pass them around, return them, hold them as their own, evaluated concept
  - This is **really not true** in languages like C, for instance
  - This makes procedures first-class in Racket
- Support for higher-order/first-class functions is one of the hallmarks of a language that supports **functional programming**

# Closures: what lambdas evaluate to

The expression of `(lambda parameters body..)` evaluates to a *closure* consisting of

- The parameter list (a list of identifiers)
- The body as un-evaluated expressions (often just one expression)
- The environment (the mapping of identifiers to values) **at the time the lambda expression is evaluated**

We'll return to this – becomes important!

# `define` + `lambda` = reusable procedures!

We can combine `define` and `lambda`, so that we can get a named procedure!

```
(define add-two  
  (lambda (x)  
    (+ x 2)))
```

To call it, we then use prefix call notation, as usual:

```
(add-two 2) will give us 4
```

# What have we learned thus far?

- How to call procedures
- Predicates
- `if`
- `cond`
- `define`
- `lambda`
- `define` & `lambda` **together!**

```
(define lily  
  (lambda (x y)  
    (string-append y x)))
```

```
(lily "hello" "?")
```

What does this code evaluate to?

- A. Error
- B. "hello?"
- C. "?hello"
- D. "hello ?"
- E. Something else

```
(define alright
  (lambda (a b)
    (cond [(equal? a b) "equal"]
          [(positive? a) 17]
          [(and (positive? a) (negative? b)) 5]
          [else "chaos!"])))
```

What does calling `(alright 10 -30)` evaluate to?

- A. "chaos"
- B. Error
- C. 5
- D. 17
- E. "equal"

# Can we use identifiers in lambdas? Sure!

**Note:** you won't see for loops in this class; recursion all the way

Computing factorial in Racket:

```
(define fact
  (lambda (num)
    (if (<= num 1)
        1
        (* num (fact (- num 1))))))
```

# A Note on Readings

*RPTFW is really a reference guide*

- If something didn't make sense in lecture? Great resource, this textbook or the additional resources I link
  - Honor Code: look it up there, not Google!
- If you want more detail about something? Readings!
- Especially Chapters 1 & 2 teach you about some great Racket operators (hint: member, remove) that we don't cover in class
- You'll read about mutability (e.g., set!), for loops and some "useful" Racket that is **not** functional style - refrain from using it and stick to what we learn in class!
- Readings/order of lecture not entirely in sync

# Next Up!

See the Schedule for Readings.
